INTRODUCTION

The Trans-Atlantic and Intra-American Slave Trade Databases contain three types of variables: 1) technical variables; 2) data variables; and 3) imputed variables. **Technical variables** separate out trans-Atlantic from Intra-American voyages, assign a unique identification number to each trans-Atlantic slaving voyage (the basic unit of analysis), keep track of changes since publication of the database on CD-ROM in 1999, and provide voyage groupings used for purposes of computing two key imputed variables, the total number of slaves embarked (SLAXIMP) and disembarked (SLAMIMP). **Data variables** comprise those variables whose values come directly from historical records. **Imputed variables** either are computed from data variables (such as slave mortality rates) or infer data not found in existing documentation on the basis of patterns observed in data variables (such as embarkations on slave voyages on ships of similar tonnage and rigging in the same period of time). Assumptions made in imputing variables are explained at some length in David Eltis, “Construction of the Trans-Atlantic Slave Trade Database: Sources and Methods” (2019), in the section “Understanding the Database” on the *Voyages* website. This codebook defines all the variables to be found in both data sets, but not all variables appear in both data sets.

The SPSS format of each variable is specified just below its label. F stands for standard numeric format, A for an alphanumeric or string variable, and DATE for dates entered as yyyy-mm-dd. The number following a letter indicates its width or the number of characters allowed for entering data. Numbers are integers except for ratios and percentages. Their print and write format is usually F8.5, indicating a width of 8 characters of which 5 follow the decimal point.

APPENDIX: GEOGRAPHICAL CODES

All geographical variables use a 5-digit set of codes where the first digit indicates broad region, the second and third digits indicate a specific region within the broad region, and the fourth and fifth digits indicate a place (port or location) within a specific region. The data variable for all geographical locations is a port or place mentioned in historical records. In general, spelling reflects the language of the region where the port or place is located during the time period of the slave trade. The terms “port” and “place” are used interchangeably. An effort has been made to combine alternative spellings into a single code so that each code represents a distinct place. A “port unspecified” code for region is used when historical records mention only a region without specifying the port or place within it. In the version of Trans- Atlantic Slave Trade Database on the *Voyages* website, region and broad region are derived automatically using the first five digits of the geographical code, as explained above.

However, in the expanded dataset, the regional code is in a few special cases different from that implied by a code for a particular place. This happens when a place was under different jurisdictions in different periods of time: for example, Jamaica and Bonaire in the sixteenth century, when they were Spanish colonies before becoming English and Dutch respectively in the seventeenth century. Other cases are Demerara and Berbice, which were Dutch before 1796 and British thereafter. In this example, the two places are coded at the regional level as Dutch and British, depending on date of arrival of slave ships, although the specific code for Berbice is within Dutch Guiana (32250) and for Demerara within the British Guianas (35304).

Non-geographical codes are used to explain, for certain variables, why geographic information is missing.
